
Certificate in Civil Structural Engineering (Portugal)

Geotechnical Engineering

Atterberg Limits – Standard tests defining the plastic and liquid limits of fine-grained soils. Liquid limit, Plastic limit, Shrinkage limit. Example: determining the consistency of a clay for pavement subgrade. Practical application: classifying soils according to the Unified Soil Classification System (USCS). Challenge: moisture content must be precisely controlled to obtain repeatable results.

Adhesion – Shear stress required to pull a soil particle away from a smooth surface. Friction angle, Cohesion. Example: calculating pull-out resistance of a geotextile in a sand fill. Practical application: design of retaining wall anchors. Challenge: variability with surface roughness and moisture.

Active Earth Pressure – Lateral pressure exerted by a soil mass when it expands laterally under the influence of gravity. Passive earth pressure, Rankine theory, Coulomb theory. Example: pressure on the back of a cantilever retaining wall. Practical application: sizing of wall reinforcement. Challenge: accurate estimation of the coefficient of active pressure (K_a) for layered soils.

Adverse Pressure Gradient – Condition where pore-water pressure decreases with depth, potentially causing soil suction. Effective stress, Suction. Example: drying of unsaturated clay in arid climates. Practical application: stability analysis of slopes. Challenge: modeling suction effects in numerical simulations.

Aggregate – Coarse particles used in concrete, sub-base, or backfill. Coarse aggregate, Fine aggregate. Example: crushed stone used as a base layer under a roadway. Practical application: providing strength and drainage. Challenge: ensuring gradation meets specifications.

Artificial Ground Improvement – Techniques that modify in-situ soil properties via engineering actions. Compaction, Soil mixing, Vibro-replacement. Example: installing stone columns to increase bearing capacity. Practical application: reducing settlement of soft clays. Challenge: cost and disturbance to existing structures.

Backfill – Material placed behind a retaining structure or within an excavated area. Granular backfill, Cohesive backfill. Example: sand placed behind a sheet pile wall. Practical application: providing lateral support. Challenge: achieving uniform compaction.

Bearing Capacity – Maximum pressure that a soil can support without failure. Ultimate bearing capacity, Allowable bearing pressure. Example: design of a shallow foundation for a small building. Practical application: selecting footing size. Challenge: accounting for variability in soil strength parameters.

Bearing Ratio – Ratio of the stress in the foundation to the stress at the ground surface. Stress distribution, Contact pressure. Example: evaluating settlement for a slab on grade. Practical application: assessing load transfer efficiency. Challenge: determining accurate stress paths in layered soils.

Bentonite – Highly plastic clay used for its low permeability and swelling properties. Swelling pressure,

Sealant. Example: liner material in a landfill. Practical application: creating an impermeable barrier. Challenge: controlling moisture content during installation.

Biostabilization – Use of biological processes to improve soil properties, such as microbial induced calcite precipitation. Microbial induced calcite precipitation, Soil cementation. Example: treating soft sand to increase stiffness. Practical application: environmentally friendly ground improvement. Challenge: ensuring uniform distribution of microorganisms.

Biot Coefficient – Ratio of the pore-water pressure change to the total stress change in a porous medium. Effective stress principle, Poromechanics. Example: calculating deformation of a saturated clay under loading. Practical application: coupled hydro-mechanical analysis. Challenge: determining accurate values for heterogeneous soils.

Blow-count Test – Field test using a dynamic cone penetrometer to assess soil strength. Dynamic cone penetrometer (DCP), Penetration resistance. Example: rapid assessment of sub-grade stiffness for road construction. Practical application: quality control of compaction. Challenge: correlation with laboratory-derived strength parameters.

Block Caving – Mining method that may affect surface geotechnics through induced subsidence. Subsidence, Ground control. Example: monitoring settlement above an underground mine. Practical application: designing foundations near mining operations. Challenge: predicting long-term ground movements.

Booster Pump – Pump used to increase pressure in dewatering systems. Dewatering, Groundwater control. Example: raising water level in a well to assist excavation. Practical application: maintaining dry work areas. Challenge: selecting appropriate capacity for variable flow rates.

Boundary Conditions – Constraints applied to a geotechnical model to simulate real-world behavior. Fixed support, Roller support. Example: applying fixed base in a finite element model of a retaining wall. Practical application: accurate simulation of soil-structure interaction. Challenge: selecting realistic constraints for complex geometries.

Bottom-up Seepage – Flow of water from a higher to lower hydraulic head through a soil layer. Darcy's law, Hydraulic gradient. Example: drainage through a compacted clay liner. Practical application: designing leachate collection systems. Challenge: estimating permeability of low-permeability soils.

Bradley's Method – Empirical approach for estimating the coefficient of earth pressure based on soil type. K_a , K_p . Example: using Bradley's values for sandy soils in wall design. Practical application: quick preliminary design. Challenge: limited applicability to non-standard soils.

Brine Stabilization – Use of saline solutions to alter soil behavior, often to reduce swelling. Swelling reduction, Chemical stabilization. Example: treating expansive clay with calcium chloride. Practical application: improving pavement subgrade performance. Challenge: environmental impacts of salt leaching.

Broad-Shear Test – Laboratory test measuring shear strength of soil over a wide area. Direct shear test,

Triaxial test. Example: assessing shear resistance of a sand-clay mix. Practical application: calibrating numerical models. Challenge: equipment size limits for large samples.

Bulk Density – Mass of dry soil per unit volume, including voids. Dry density, Moisture content. Example: measuring in-situ density of a compacted embankment. Practical application: verifying compaction specifications. Challenge: accounting for moisture variations during testing.

Buoyancy Force – Upward force exerted by a fluid on a submerged object, equal to the weight of displaced fluid. Effective stress, Pore pressure. Example: uplift of a shallow foundation in high water table conditions. Practical application: designing anchors for submerged structures. Challenge: predicting transient water level changes.

Buried Pipe – Pipeline installed beneath the ground surface, requiring soil interaction analysis. Trench backfill, Soil cover. Example: water main placed 1 m deep under a road. Practical application: assessing settlement and load transfer. Challenge: ensuring trench stability during installation.

Buried Utility – Infrastructure such as cables or pipes that must be protected from ground movements. Soil-structure interaction, Protective bedding. Example: telecom fiber optic cable laid under a highway. Practical application: designing flexible joints to accommodate differential settlement. Challenge: locating existing utilities accurately.

Cam Clay Model – Constitutive model describing the elasto-plastic behavior of normally consolidated clays. Yield surface, Hardening. Example: simulating settlement of a clay embankment. Practical application: advanced numerical analysis of clay behavior. Challenge: calibrating model parameters from laboratory tests.

Capillary Rise – Height to which water can rise in a soil due to surface tension and pore size. Suction, Unsaturated flow. Example: moisture migration into a foundation footing from below ground water. Practical application: design of waterproofing systems. Challenge: predicting capillary effects in heterogeneous soils.

Carbonate Cementation – Process where carbonate minerals precipitate and bind soil particles, increasing strength. Biocementation, Soil stabilization. Example: treating loose sand with calcium carbonate solution. Practical application: environmentally friendly ground improvement. Challenge: controlling precipitation uniformity.

Case Study – Detailed examination of a specific geotechnical project used for teaching and research. Project documentation, Lessons learned. Example: analysis of a landslide that affected a highway. Practical application: illustrating real-world problem solving. Challenge: ensuring relevance to curriculum objectives.

Cavern Stability – Assessment of the ability of underground openings to remain intact under stress. Rock mass rating, Support design. Example: evaluating a limestone cavern used for storage. Practical application: designing rock bolts and lining. Challenge: accounting for time-dependent rock behavior.

Centroid – Geometric center of a soil element used in calculating resultant forces. Resultant force, Moment

arm. Example: determining the point of action of earth pressure on a retaining wall. Practical application: accurate structural analysis. Challenge: complex shapes requiring integration.

Ceiling Effect – Phenomenon where increasing a parameter yields diminishing returns, such as in densification of highly compacted soils. Compaction, Soil density. Example: additional compaction passes on a well-compacted sand layer. Practical application: optimizing construction schedules. Challenge: recognizing when further effort is non-productive.

Chezy Coefficient – Empirical factor used to estimate flow velocity in open channels, sometimes applied to seepage analysis. Darcy-Weisbach, Manning's n . Example: calculating water flow through a drainage ditch. Practical application: design of surface drainage. Challenge: selecting appropriate value for roughness.

Clayey Soil – Soil containing a high proportion of clay particles, exhibiting low permeability and high plasticity. Plasticity index, Cohesion. Example: foundation soil for a low-rise building. Practical application: assessing settlement potential. Challenge: sensitivity to moisture changes.

Coarse Grained Soil – Soil dominated by sand, gravel, or stone particles, typically having higher permeability. Grain size distribution, Permeability. Example: backfill material for a retaining wall. Practical application: rapid drainage. Challenge: controlling gradation to prevent segregation.

Coastal Erosion – Process of shoreline retreat that can affect geotechnical stability of near-shore structures. Wave action, Sediment transport. Example: designing a revetment to protect a road embankment. Practical application: mitigation measures. Challenge: predicting long-term shoreline changes.

Coefficient of Consolidation (C_v) – Parameter describing the rate at which a saturated soil consolidates under load. Time factor, One-dimensional consolidation. Example: estimating settlement time for a building foundation. Practical application: construction scheduling. Challenge: variability with stress history.

Coefficient of Earth Pressure (K) – Ratio of horizontal to vertical effective stress in a soil mass. K_a , K_p . Example: calculating active pressure on a retaining wall. Practical application: structural design. Challenge: selecting appropriate theory for layered soils.

Coefficient of Thermal Expansion – Ratio describing the change in soil volume with temperature. Thermal strain, Soil temperature. Example: expansion of clayey fill during summer. Practical application: design of joints in pavement. Challenge: limited data for many soils.

Compaction – Process of increasing soil density by reducing void space through mechanical work. Proctor test, Field density. Example: compacting a sub-grade for a highway. Practical application: improving load-bearing capacity. Challenge: achieving uniform density across large areas.

Compaction Curve – Graph showing maximum dry density versus optimum moisture content for a given soil. Proctor test, Relative compaction. Example: selecting water content for field compaction. Practical application: quality control. Challenge: variations in field conditions.

Consolidation – Time-dependent settlement of saturated soils due to expulsion of pore water under load. C_v , One-dimensional consolidation. Example: settlement of a clay foundation. Practical application:

predicting long-term deformations. Challenge: accounting for layered systems.

Confining Pressure – Isotropic stress applied to a soil specimen during testing. Triaxial test, Effective stress. Example: setting a 100 kPa confining pressure in a triaxial cell. Practical application: simulating in-situ stress conditions. Challenge: replicating field stress paths.

Construction Soil – Soil excavated or placed during construction activities, often requiring testing for suitability. Borrow material, Fill material. Example: using on-site excavated material for backfill. Practical application: cost reduction. Challenge: ensuring material meets specifications.

Contact Pressure – Pressure transmitted through the interface between a foundation and the supporting soil. Stress distribution, Bearing capacity. Example: pressure under a spread footing. Practical application: checking for soil bearing limits. Challenge: non-uniform pressure due to eccentric loading.

Continuum Mechanics – Branch of mechanics dealing with the behavior of continuous materials, forming the basis of many geotechnical models. Stress-strain relationship, Constitutive models. Example: applying elasticity theory to soil deformation. Practical application: finite element analysis. Challenge: representing discrete particle behavior in a continuum framework.

Controlled Modulus Column (CMC) – Ground improvement technique using prefabricated concrete columns with a prescribed modulus. Stone column, Deep mixing. Example: installing CMCs beneath a soft clay embankment. Practical application: reducing settlement. Challenge: controlling column stiffness during installation.

Corrosion – Degradation of metal components in contact with soil, affecting the durability of foundations and anchors. Reinforcement, Protective coating. Example: corrosion of steel piles in aggressive soil. Practical application: material selection. Challenge: predicting service life in varied soil chemistries.

Cracking (in Clay) – Development of tensile fractures due to drying shrinkage or temperature changes. Desiccation, Shrinkage. Example: cracks forming in a clay liner of a landfill. Practical application: monitoring barrier integrity. Challenge: modeling crack propagation.

Critical State Soil Mechanics – Theory describing the condition where soil deforms continuously without changes in stress or volume. Cam Clay model, Yield surface. Example: analyzing the ultimate strength of a normally consolidated clay. Practical application: advanced constitutive modeling. Challenge: parameter identification from limited laboratory data.

Cross-Sectional Area – Area of a soil element perpendicular to the direction of load, used in stress calculations. Stress, Load intensity. Example: calculating stress on a retaining wall stem. Practical application: structural analysis. Challenge: complex geometries requiring integration.

Cut-and-Cover Tunnel – Underground passage constructed by excavating a trench, installing the tunnel, and backfilling. Ground support, Settlement. Example: building a subway segment beneath a city. Practical application: assessing surface settlement. Challenge: controlling ground movement to protect adjacent structures.

Cutoff Wall – Impermeable barrier constructed to limit groundwater flow, often made of concrete or slurry. Diaphragm wall, Sheet pile. Example: installing a cutoff wall beneath a dam foundation. Practical application: reducing seepage. Challenge: ensuring continuity and low permeability.

Damage Zone – Region of disturbed soil surrounding a pile or foundation due to installation stresses. Soil disturbance, Pile driving. Example: reduced shear strength around a driven steel pile. Practical application: adjusting design for loss of capacity. Challenge: quantifying extent in the field.

Deformation Modulus (E_s) – Soil stiffness parameter obtained from plate load tests, representing the relationship between stress and settlement. Plate bearing test, Settlement. Example: measuring E_s of a sand layer for foundation design. Practical application: predicting settlement under loads. Challenge: variability with test size and boundary effects.

Deformation Ratio – Ratio of vertical settlement to horizontal displacement in a soil mass. Settlement, Lateral movement. Example: assessing differential settlement of a slab on grade. Practical application: design of flexible pavement. Challenge: accurate field measurement.

Delamination – Separation between layers in a composite soil-structure system, often due to inadequate bonding. Bond strength, Interface shear. Example: delamination of a geotextile from surrounding sand. Practical application: checking reinforcement effectiveness. Challenge: detection without invasive methods.

Dense Sand – Sand with a high relative density, typically exhibiting high stiffness and strength. Relative density, Granular material. Example: backfill material for a retaining wall. Practical application: providing resistance to lateral loads. Challenge: maintaining density during placement.

Design Earthquake – Specified seismic event used for structural and geotechnical design. Seismic coefficient, Pseudo-static analysis. Example: using a 0.15g design earthquake for a low-rise building. Practical application: sizing foundations for seismic loads. Challenge: selecting appropriate spectral accelerations for site conditions.

Design Load – Combination of forces considered in the design of a foundation or earth structure. Dead load, Live load, Seismic load. Example: applying a load factor of 1.5 to the sum of dead and live loads. Practical application: ensuring safety margins. Challenge: accounting for load combinations in complex projects.

Design Soil Profile – Stratigraphic description of subsurface conditions used for engineering analysis. Geotechnical report, Borehole logs. Example: a profile showing 2 m of fill over 5 m of soft clay. Practical application: foundation selection. Challenge: variability between boreholes.

Deformation Plate Test – Field test where a rigid plate is loaded on the ground surface to assess settlement characteristics. Plate bearing test, Modulus of subgrade reaction. Example: evaluating the stiffness of a road subgrade. Practical application: determining design parameters for pavement. Challenge: interpreting results for layered soils.

Deformation Settlement – Immediate settlement occurring as a result of elastic deformation under load.

Elastic settlement, Immediate settlement. Example: settlement of a shallow foundation during construction. Practical application: short-term performance assessment. Challenge: distinguishing from consolidation settlement.

Deformation Theory – Constitutive approach assuming that stress depends only on current strain, not on loading history. Elastic-perfectly plastic, Non-linear elasticity. Example: using deformation theory for quick analysis of a retaining wall. Practical application: simplified design calculations. Challenge: limited accuracy for cyclic loading.

Deformation Velocity – Rate at which a soil mass changes shape under applied loads. Strain rate, Creep. Example: monitoring creep of a soft clay embankment. Practical application: long-term stability assessment. Challenge: measuring small rates over long periods.

Deformation Index – Parameter indicating the susceptibility of a soil to deformation under load. Modulus, Settlement coefficient. Example: using a deformation index to compare different backfill materials. Practical application: material selection. Challenge: standardizing test methods.

Deflection – Displacement of a structural element or soil mass under load. Vertical deflection, Lateral deflection. Example: deflection of a bridge pier due to soil settlement. Practical application: serviceability checks. Challenge: separating soil-induced deflection from structural movement.

Delamination Test – Laboratory test to evaluate the bonding strength between a geosynthetic and surrounding soil. Pull-out test, Shear test. Example: measuring the pull-out resistance of a geotextile in sand. Practical application: design of reinforcement systems. Challenge: replicating field conditions.

Denitrification – Biological process reducing nitrate in groundwater, potentially influencing soil chemistry. Soil chemistry, Groundwater quality. Example: nitrate removal in a landfill leachate plume. Practical application: environmental monitoring. Challenge: predicting impact on geotechnical properties.

Density Index (ID) – Ratio of the in-situ dry density to the maximum dry density obtained from a standard compaction test. Relative density, Compaction. Example: achieving an ID of 85 % for a road subgrade. Practical application: quality assurance. Challenge: moisture control during testing.

Depth of Influence – Extent to which a load or stress affects the underlying soil mass. Stress distribution, Settlement. Example: estimating depth of influence for a shallow footing using empirical formulas. Practical application: design of foundations. Challenge: complex for layered soils.

Desiccation Cracks – Cracks formed in clay soils due to drying and shrinkage. Swelling, Shrinkage. Example: cracks appearing on a landfill liner after a dry season. Practical application: monitoring liner integrity. Challenge: predicting crack patterns.

Design Factor of Safety – Ratio of the capacity of a system to the applied load, used to ensure reliability. Safety factor, Reliability. Example: using a factor of 1.5 for bearing capacity of a shallow foundation. Practical application: risk management. Challenge: balancing safety with cost.

Design Shear Strength – Shear resistance of soil used in design calculations, incorporating safety factors. c' ,

ϕ' , Effective stress. Example: using a design shear strength of 30 kPa for a sand backfill. Practical application: retaining wall analysis. Challenge: variability in in-situ conditions.

Design Water Table – Assumed groundwater level used for design of foundations and earth structures. Groundwater control, Seepage. Example: using a design water table 1 m below ground for a residential building. Practical application: settlement prediction. Challenge: seasonal fluctuations.

Design Bearing Pressure – Maximum pressure that a foundation may exert on the soil without exceeding allowable limits. Allowable bearing pressure, Ultimate bearing capacity. Example: limiting pressure to 150 kPa for a spread footing. Practical application: footing size determination. Challenge: accounting for load eccentricity.

Design Life – Expected service period for a geotechnical structure, influencing material selection and performance criteria. Durability, Maintenance. Example: designing a landfill liner for a 50-year design life. Practical application: long-term monitoring plans. Challenge: predicting future environmental conditions.

Design Seismic Coefficient – Factor used to represent seismic forces in static analysis of foundations. Seismic load, Pseudo-static analysis. Example: applying a seismic coefficient of 0.1g for a low-rise building. Practical application: simple seismic design. Challenge: limited representation of dynamic effects.

Design Soil Profile – (see earlier entry).

Design Load Combination – Set of loads combined according to code provisions for design checks. Gravity loads, Seismic loads, Wind loads. Example: $1.2 \times \text{Dead} + 1.5 \times \text{Live}$ for ultimate limit state. Practical application: structural and foundation design. Challenge: ensuring appropriate combinations for geotechnical aspects.

Design Water Table – (see earlier entry).

Design Earthquake – (see earlier entry).

Design Factor of Safety – (see earlier entry).

Design Shear Strength – (see earlier entry).

Design Bearing Pressure – (see earlier entry).

Design Load – (see earlier entry).

Design Load Combination – (see earlier entry).
