

Regulatory Frameworks for AI in Health Care

Algorithmic Transparency – Related terms: Explainability, auditability, model documentation. A principle requiring that the logic, data sources, and decision pathways of AI systems be openly described. Example: Publishing a model card for a diagnostic algorithm. Practical application: Clinicians can assess why a risk score was assigned. Challenges include proprietary code protection and the technical difficulty of simplifying complex models.

Artificial Intelligence (AI) – Related terms: Machine learning, deep learning, neural networks. The broader field of computer systems that perform tasks requiring human-like intelligence. Example: An AI-driven chatbot triaging patient symptoms. Practical application: Automating routine administrative tasks. Challenges involve ensuring safety, ethical use, and regulatory compliance.

Artificial Intelligence Act (EU) – Related terms: EU AI Regulation, conformity assessment, high-risk AI. The European Union's legislative proposal establishing a risk-based framework for AI applications, including health care. Example: A medical imaging AI classified as high-risk must undergo a conformity assessment before market entry. Practical application: Provides a unified legal standard across member states. Challenges include interpreting ambiguous definitions and aligning with existing national regulations.

Beneficence Assessment – Related terms: Risk-benefit analysis, clinical justification, patient welfare. The evaluation of whether an AI system's intended benefits outweigh potential harms. Example: Assessing whether a predictive model for sepsis improves outcomes without increasing false alarms. Practical application: Informs ethical review boards. Challenges arise from limited real-world performance data.

Clinical Decision Support (CDS) Software – Related terms: Medical device software, health-IT, decision aid. Software that provides health professionals with patient-specific assessments or recommendations. Example: An AI-based tool suggesting antibiotic choices based on pathogen data. Practical application: Enhances diagnostic accuracy. Challenges include integration with electronic health records (EHRs) and meeting medical device regulations.

Clinical Evaluation – Related terms: Performance validation, post-market surveillance, safety monitoring. Systematic assessment of an AI system's safety and effectiveness in a clinical setting. Example: A multicenter trial measuring the sensitivity of an AI skin-lesion classifier. Practical application: Required for regulatory approval. Challenges involve obtaining representative datasets and addressing data drift over time.

Compliance Pathway – Related terms: Regulatory submission, conformity assessment, certification. The set of steps an AI health product must follow to meet legal requirements. Example: A manufacturer follows the FDA's De Novo pathway for a novel AI algorithm. Practical application: Guides product development timelines. Challenges include navigating differing international standards.

Conformity Assessment – Related terms: CE marking, notified body, standards compliance. The process of

demonstrating that an AI device meets applicable regulatory requirements. Example: A notified body evaluates a machine-learning-based cardiac monitor for CE marking. Practical application: Enables market access in the European Economic Area. Challenges include resource-intensive testing and evolving standards.

Data Governance – Related terms: Data stewardship, data quality, data lifecycle. The framework for managing data assets to ensure integrity, privacy, and appropriate use. Example: A hospital establishes a data-sharing agreement for training AI models. Practical application: Supports compliance with GDPR and HIPAA. Challenges involve aligning multiple stakeholders and maintaining data provenance.

Data Minimisation – Related terms: Privacy by design, purpose limitation, anonymisation. The principle of collecting only the data necessary for a specific purpose. Example: An AI tool for predicting readmission uses age, comorbidities, and discharge disposition, excluding unrelated identifiers. Practical application: Reduces privacy risk. Challenges include balancing model performance with limited data.

Data Privacy Impact Assessment (DPIA) – Related terms: Privacy impact assessment, risk assessment, GDPR. A systematic process to identify and mitigate privacy risks of data processing activities. Example: A DPIA for an AI-driven mental-health app identifies potential re-identification risks. Practical application: Required under GDPR for high-risk processing. Challenges include accurately forecasting future AI uses.

Data Provenance – Related terms: Data lineage, audit trail, metadata. Documentation of the origin, transformations, and handling of data used to train or operate AI systems. Example: A provenance record shows that a chest-X-ray dataset was sourced from a specific hospital and cleaned using defined scripts. Practical application: Supports reproducibility and regulatory audits. Challenges include maintaining comprehensive metadata across multiple pipelines.

Data Quality Assurance – Related terms: Data cleaning, validation, error detection. Processes to ensure that data used for AI development are accurate, complete, and fit for purpose. Example: Implementing automated checks for missing values in a training set of lab results. Practical application: Improves model reliability. Challenges involve detecting subtle biases that may not be obvious through standard checks.

De-identification – Related terms: Anonymisation, pseudonymisation, privacy protection. Techniques to remove or mask personal identifiers from health data. Example: Replacing patient IDs with random tokens before sharing data with a research consortium. Practical application: Facilitates data sharing while complying with privacy laws. Challenges include the risk of re-identification through data linkage.

De Novo Classification – Related terms: FDA pathway, novel device, risk classification. A regulatory route in the United States for novel medical devices of low to moderate risk that lack a predicate. Example: An AI algorithm for early detection of diabetic retinopathy receives De Novo clearance. Practical application: Provides a path for innovative AI products. Challenges include demonstrating substantial equivalence without a prior device.

Device Software as a Medical Device (SaMD) – Related terms: Medical device, software classification, IEC 62304. Software intended to perform medical functions without being part of a hardware device. Example: A cloud-based AI tool that predicts stroke risk. Practical application: Regulated similarly to physical devices.

Challenges involve defining intended use and meeting software lifecycle standards.

Digital Therapeutics (DTx) – Related terms: Health app, regulatory approval, therapeutic claim. Software-based interventions that deliver evidence-based therapeutic outcomes. Example: An AI-guided cognitive-behavioral therapy app for anxiety. Practical application: May be reimbursed as a prescription product. Challenges include demonstrating clinical efficacy and navigating both medical device and drug regulations.

Ethical AI Framework – Related terms: Responsible AI, AI ethics, governance. Structured guidance for developing AI systems that respect ethical principles such as fairness, accountability, and transparency. Example: A hospital adopts an ethical AI charter to guide AI procurement. Practical application: Aligns AI projects with institutional values. Challenges include translating abstract principles into concrete operational controls.

Explainability – Related terms: Interpretability, model transparency, post-hoc analysis. The degree to which a human can understand the reasoning behind an AI system's output. Example: Using SHAP values to illustrate which features contributed to a high-risk cancer prediction. Practical application: Builds clinician trust. Challenges include trade-offs with model complexity and performance.

FDA 510(k) Clearance – Related terms: Predicate device, premarket notification, regulatory submission. The US pathway for demonstrating that a new device is substantially equivalent to an existing legally marketed device. Example: An AI-enhanced ECG interpretation tool submits a 510(k) using a previously cleared ECG analyzer as a predicate. Practical application: Faster market entry compared with premarket approval. Challenges include identifying an appropriate predicate and meeting specific performance criteria.

FDA Pre-Market Approval (PMA) – Related terms: High-risk device, clinical trial, regulatory review. The most stringent US pathway requiring evidence of safety and effectiveness. Example: An AI system for autonomous robotic surgery undergoes PMA review. Practical application: Ensures thorough evaluation for high-risk AI. Challenges include extensive data requirements and longer timelines.

Fairness Assessment – Related terms: Bias detection, equity analysis, demographic parity. Systematic evaluation of whether an AI system's outcomes are equitable across protected groups. Example: Testing a predictive model for heart failure across age, gender, and ethnicity to detect disparate impact. Practical application: Informs mitigation strategies before deployment. Challenges involve defining appropriate fairness metrics and reconciling them with clinical accuracy.

General Data Protection Regulation (GDPR) – Related terms: EU privacy law, data subject rights, lawful basis. EU regulation governing personal data processing, including health data. Example: An AI-driven telehealth platform must obtain explicit consent for processing patient images. Practical application: Sets a high bar for privacy compliance worldwide. Challenges include interpreting "special category" data provisions for health and aligning with AI-specific obligations like DPIA.

Health Level Seven (HL7) FHIR – Related terms: Interoperability, API standards, data exchange. A set of standards for exchanging electronic health information. Example: An AI service accesses patient lab results via a FHIR API to generate risk scores. Practical application: Facilitates real-time integration of AI into EHRs.

Challenges include ensuring consistent implementation across vendors and handling versioning.

Human-in-the-Loop (HITL) – Related terms: Oversight, collaborative AI, decision augmentation. Design approach where clinicians review or modify AI outputs before final action. Example: A radiology AI flags suspicious nodules, but a radiologist confirms the diagnosis. Practical application: Balances automation with clinical expertise. Challenges include workflow disruption and potential over-reliance on AI suggestions.

Impact Assessment (IA) – Related terms: Risk assessment, benefit analysis, stakeholder analysis. A systematic process to evaluate the potential effects of deploying an AI system, including social, economic, and health outcomes. Example: An IA for a population-wide AI screening program examines cost savings versus privacy concerns. Practical application: Informs policymakers and funding bodies. Challenges include quantifying intangible impacts and incorporating diverse stakeholder perspectives.

International Medical Device Regulators Forum (IMDRF) – Related terms: Global harmonisation, regulatory guidance, risk classification. A voluntary group of medical device regulators that develops common standards. Example: IMDRF’s “Software as a Medical Device” guidance informs national policies. Practical application: Promotes consistent regulatory expectations across regions. Challenges include translating consensus documents into enforceable national law.

International Organization for Standardization (ISO) 14971 – Related terms: Risk management, medical device safety, ISO standards. The ISO standard for risk management of medical devices, including AI-based devices. Example: Applying ISO 14971 to identify hazards of an AI-driven insulin dosing algorithm. Practical application: Provides a structured risk analysis framework. Challenges involve adapting the standard to dynamic, data-driven risk profiles.

ISO 13485 – Related terms: Quality management system, medical device manufacturing, compliance. The ISO standard for quality management systems specific to medical devices. Example: A software firm implements ISO 13485 processes for AI model version control. Practical application: Supports regulatory submissions and audits. Challenges include integrating software-centric activities into a traditionally hardware-focused QMS.

ISO/IEC 27001 – Related terms: Information security, risk management, data protection. The standard for establishing, implementing, and maintaining an information security management system. Example: A health-AI startup obtains ISO/IEC 27001 certification to assure partners of data security. Practical application: Mitigates cyber-risk for AI systems handling sensitive health data. Challenges include continuous monitoring and adapting to evolving threat landscapes.

Joint Commission Accreditation – Related terms: Healthcare quality, accreditation standards, patient safety. The US body that accredits health organizations based on performance standards. Example: A hospital must demonstrate compliance with AI safety protocols to maintain accreditation. Practical application: Encourages consistent quality across institutions. Challenges include aligning AI governance with existing accreditation criteria.

Knowledge Transfer – Related terms: Training, capacity building, dissemination. The process of moving AI expertise from developers to clinicians and administrators. Example: Workshops teaching clinicians how to

interpret AI-generated risk scores. Practical application: Improves adoption and appropriate use. Challenges include varying levels of digital literacy and resource constraints.

Legal Liability – Related terms: Negligence, product liability, accountability. The legal responsibility for harms caused by AI systems. Example: Determining whether a manufacturer or a physician is liable when an AI misclassifies a tumor. Practical application: Influences contract terms and insurance coverage. Challenges include ambiguous causation chains and cross-jurisdictional differences.

Machine Learning (ML) – Related terms: Supervised learning, unsupervised learning, reinforcement learning. A subset of AI focused on algorithms that improve performance through data exposure. Example: A gradient-boosted tree model predicting hospital readmission risk. Practical application: Enables data-driven clinical predictions. Challenges involve model drift, interpretability, and data quality.

Medical Device Regulation (MDR) – EU – Related terms: CE marking, classification, conformity assessment. The European Union’s regulatory framework replacing the previous Medical Devices Directive. Example: An AI-based diagnostic tool classified as Class IIa must undergo a notified-body assessment for CE marking. Practical application: Ensures safety and performance across EU markets. Challenges include extensive documentation and post-market surveillance obligations.

Model Drift – Related terms: Concept drift, performance degradation, monitoring. The phenomenon where an AI model’s accuracy declines over time due to changes in data distribution. Example: An AI sepsis predictor trained on pre-COVID data performs poorly during pandemic spikes. Practical application: Triggers re-training or recalibration. Challenges include detecting subtle drift and allocating resources for continuous updates.

Model Governance – Related terms: Model lifecycle, version control, oversight. Structured policies and procedures governing the development, deployment, and retirement of AI models. Example: A governance board reviews each new version of a predictive model before release. Practical application: Ensures consistency, compliance, and accountability. Challenges involve coordinating multidisciplinary stakeholders and maintaining traceability.

Model Interpretability – Related terms: Explainability, transparency, feature importance. The extent to which humans can comprehend how an AI model arrives at a specific output. Example: Using LIME to highlight image regions influencing a cancer detection AI. Practical application: Supports clinical validation and regulatory review. Challenges include balancing interpretability with predictive performance.

Neural Network Architecture – Related terms: Deep learning, layers, parameters. The structural design of a neural network, defining how neurons are arranged and connected. Example: A U-Net architecture for segmentation of MRI scans. Practical application: Determines suitability for specific imaging tasks. Challenges include computational cost and overfitting risk.

Non-Clinical Validation – Related terms: Bench testing, simulation, synthetic data. Evaluation of AI performance using controlled, non-patient data sources. Example: Testing a diagnostic AI on a synthetic dataset generated from a generative model. Practical application: Early risk identification before human trials. Challenges include ensuring synthetic data faithfully represents real-world variability.

Notified Body – Related terms: Conformity assessment, CE marking, EU regulator. An organization designated by EU member states to assess conformity of certain products, including medical devices. Example: A notified body audits an AI-enabled cardiac monitor for CE compliance. Practical application: Provides independent verification of safety. Challenges include limited capacity and varying expertise in AI assessments.

Patient Consent – Related terms: Informed consent, opt-in, data use agreement. The process by which patients authorize the collection and processing of their health data for AI purposes. Example: A digital health platform obtains explicit consent for using wearable data in predictive analytics. Practical application: Satisfies legal and ethical obligations. Challenges include ensuring comprehension and managing withdrawal requests.

Post-Market Surveillance (PMS) – Related terms: Vigilance, real-world evidence, monitoring. Ongoing collection and analysis of data on a device's performance after it enters the market. Example: Tracking adverse events associated with an AI-driven diagnostic tool through a national registry. Practical application: Identifies safety signals and informs updates. Challenges involve data integration from disparate sources and timely analysis.

Predictive Analytics – Related terms: Risk stratification, forecasting, machine learning. Use of statistical techniques and AI to anticipate future clinical events. Example: A model forecasting 30-day readmission risk for heart failure patients. Practical application: Informs proactive care plans. Challenges include handling imbalanced outcomes and ensuring actionable insights.

Privacy by Design – Related terms: Data minimisation, encryption, GDPR. Embedding privacy considerations into the development lifecycle of AI systems. Example: Designing an AI platform that stores data in encrypted containers and limits access to only necessary personnel. Practical application: Reduces regulatory risk. Challenges include balancing privacy safeguards with model performance.

Regulatory Sandbox – Related terms: Innovation hub, pilot, exemption. A controlled environment where AI health technologies can be tested under relaxed regulatory conditions. Example: A UK sandbox allows a startup to trial an AI triage tool in selected clinics. Practical application: Accelerates innovation while monitoring safety. Challenges include defining exit criteria and ensuring patient protection.

Risk Management – Related terms: Hazard analysis, mitigation, ISO 14971. Systematic identification, evaluation, and control of risks associated with AI systems. Example: A risk matrix identifies potential misdiagnosis as a high-severity risk and implements a double-check protocol. Practical application: Satisfies regulatory expectations. Challenges include quantifying low-probability but high-impact events.

Regulatory Compliance – Related terms: Legal adherence, standards, audit. The state of meeting all applicable laws, regulations, and standards for AI health products. Example: A company conducts regular audits to verify alignment with FDA, GDPR, and ISO standards. Practical application: Avoids penalties and market restrictions. Challenges include keeping pace with rapidly evolving regulations.

Reimbursement Pathways – Related terms: Insurance coverage, coding, value-based care. Mechanisms through which AI-enabled services are financially compensated. Example: An AI-driven diabetic retinopathy

screening receives CPT code reimbursement after CMS approval. Practical application: Supports sustainable business models. Challenges involve demonstrating cost-effectiveness and navigating payer policies.

Responsible AI – Related terms: Ethical AI, governance, accountability. A framework ensuring AI systems are developed and deployed in a socially beneficial, transparent, and trustworthy manner. Example: A hospital adopts a responsible AI policy that mandates bias audits and stakeholder engagement. Practical application: Builds public trust and aligns with regulatory expectations. Challenges include operationalising high-level principles.

Safety-Critical AI – Related terms: High-risk AI, medical device, life-support. AI systems whose failure could result in serious injury or death. Example: An AI algorithm controlling infusion pump dosage. Practical application: Subject to stringent regulatory scrutiny. Challenges involve rigorous validation, redundancy, and fail-safe mechanisms.

Security Vulnerability Assessment – Related terms: Penetration testing, threat modeling, ISO/IEC 27001. Evaluation of potential weaknesses that could be exploited to compromise an AI system. Example: Testing an AI server for injection attacks. Practical application: Informs remediation before deployment. Challenges include staying ahead of sophisticated cyber threats.

Software Lifecycle Management – Related terms: Version control, continuous integration, IEC 62304. Structured approach to developing, maintaining, and retiring software. Example: Employing Git for tracking changes in an AI model pipeline. Practical application: Ensures traceability and compliance. Challenges include coordinating frequent updates with regulatory documentation.

Stakeholder Engagement – Related terms: Patient involvement, clinician input, governance. Active participation of all interested parties in AI development and oversight. Example: Forming a patient advisory board for an AI mental-health platform. Practical application: Surfaces concerns early and improves acceptance. Challenges include balancing diverse priorities and managing expectations.

Standard Operating Procedure (SOP) – Related terms: Process documentation, compliance, workflow. Written instructions detailing how to perform specific tasks consistently. Example: An SOP for validating AI model performance before each software release. Practical application: Reduces variability and supports audits. Challenges involve keeping SOPs current with rapid AI advances.

Statistical Validation – Related terms: Hypothesis testing, confidence interval, performance metrics. Application of statistical methods to assess AI model accuracy and reliability. Example: Calculating the area under the ROC curve for a diagnostic AI and reporting 95% confidence intervals. Practical application: Provides quantitative evidence for regulatory submissions. Challenges include selecting appropriate metrics for clinical relevance.

Supervised Learning – Related terms: Labeled data, classification, regression. Machine-learning approach where models learn from input-output pairs. Example: Training a neural network to classify CT scans as malignant or benign using radiologist-annotated images. Practical application: Common method for diagnostic AI. Challenges include obtaining high-quality labeled data and avoiding overfitting.

Surveillance Reporting – Related terms: Adverse event reporting, PMS, vigilance. Formal communication of safety or performance issues to regulatory authorities. Example: Submitting a field safety corrective action report for an AI-driven insulin dosing system after a dosing error. Practical application: Fulfills legal obligations and protects patients. Challenges include timely detection and accurate root-cause analysis.

Technical Documentation – Related terms: Product dossier, design file, regulatory submission. Comprehensive collection of evidence supporting a device's safety, performance, and compliance. Example: A technical file containing algorithm description, validation studies, risk analysis, and user manuals for an AI cardiac monitor. Practical application: Required for CE marking and FDA submissions. Challenges involve maintaining up-to-date documentation amid rapid AI iteration.

Therapeutic AI – Related terms: Digital therapeutics, treatment algorithm, clinical outcome. AI systems that directly influence patient treatment decisions or deliver therapy. Example: An AI that personalises chemotherapy dosing based on genomic data. Practical application: Can improve efficacy and reduce side effects. Challenges include stringent efficacy evidence and regulatory classification as a high-risk device.

Training Data Set – Related terms: Dataset, ground truth, data curation. The collection of examples used to teach an AI model. Example: A curated set of 10,000 annotated dermatology images for skin-cancer detection. Practical application: Determines model performance ceiling. Challenges include bias, representativeness, and consent for data use.

Unsupervised Learning – Related terms: Clustering, dimensionality reduction, anomaly detection. Machine-learning methods that infer patterns without labeled outcomes. Example: Using autoencoders to detect abnormal ECG patterns. Practical application: Useful for discovering unknown disease phenotypes. Challenges include interpreting results and ensuring clinical relevance.

Validation Cohort – Related terms: External validation, test set, generalisation. A separate group of patients used to assess the performance of an AI model after training. Example: Validating a sepsis prediction model on data from a different hospital network. Practical application: Demonstrates generalisability and robustness. Challenges include data access agreements and heterogeneity across sites.

Version Control – Related terms: Git, repository, change management. System for tracking modifications to code, data, and model artifacts. Example: Tagging each AI model release with a semantic version number. Practical application: Enables reproducibility and audit trails. Challenges involve managing large binary files such as imaging datasets.

Vigilance System – Related terms: Post-market surveillance, adverse event reporting, regulatory monitoring. Structured process for detecting and responding to safety issues after a product is on the market. Example: A national vigilance database records incidents linked to an AI radiology tool. Practical application: Ensures ongoing patient safety. Challenges include timely data collection and cross-border coordination.

White-Box Model – Related terms: Interpretable model, rule-based system, transparency. AI models whose internal logic is directly understandable, such as decision trees or linear regression. Example: A logistic regression model predicting stroke risk with clearly defined coefficients. Practical application: Facilitates regulatory review and clinician acceptance. Challenges include limited ability to capture complex patterns

compared with deep-learning models.
